Clinical Traits

These clinical genetic traits can inform clinical decisions and diagnoses. These traits do not predict a disease state or increased risk for disease. We currently assess one clinical trait: Alanine Aminotransferase Activity.

Alanine Aminotransferase Activity result: Low Normal

██████ has one copy of a mutation associated with reduced ALT activity as measured on veterinary blood chemistry panels. Please inform your veterinarian that ██████ has this genotype, as ALT is often used as an indicator of liver health and ██████ is likely to have a lower than average resting ALT activity. As such, an increase in ██████ ALT activity could be evidence of liver damage, even if it is within normal limits by standard ALT reference ranges.

More information on Alanine Aminotransferase Activity:

This result helps your vet understand what your dog's baseline ALT activity is. The enzyme alanine aminotransferase, or ALT, is commonly used to evaluate liver health. Dogs with one or more copies of the "A" allele are likely to have a lower baseline ALT activity ("low normal") than dogs with zero copies of the "A" allele ("normal"). This means that you and your vet might adjust what you consider your dog's baseline ALT levels to be, and consider deviations from this as "abnormal." Please note that this mutation should never increase your dog's ALT activity. If your dog has high ALT activity, please consult your veterinarian.

Health Report

How to interpret these results:

AT RISK status: Testing positive (AT RISK) is predictive of your dog being affected by this condition, but it is not a final diagnosis nor does it predict when symptoms may occur or the severity of a condition in your dog.

CARRIER status: This indicates the dog has inherited a recessive allele for a genetic trait or mutation. This is not enough to cause symptoms of the disease, but is important to bear in mind if the dog ever has offspring.

Conditions:

 Not AT RISK for any conditions tested.

Carrier

System: **Other Systems**

Condition: **Persistent Mullerian Duct Syndrome (AMHR2)**

Genotype: **CT = Carrier** (Possible Genotypes: CC = Clear , **CT = Carrier** , TT = At Risk)

Mode of Inheritance: **Recessive**

A developmental syndrome of the Miniature and Standard Schnauzers, this causes male dogs to develop parts of the female reproductive tract, which understandably can cause significant complications later in life. Female dogs with PMDS have zero anatomic abnormalities. PMDS males are quite normal as far as their male external genitalia goes, though 50% will have one or two undescended testes (unilateral or bilateral cryptorchidism), which can affect fertility and increase risk for testicular tumors. PMDS dogs can also suffer from complications of their persistent uterus, including pyometra or hydrometra (pus or fluid-filled uterus) and endometritis (inflammation of the uterine lining); symptoms for these could range from abdominal swelling to abnormal behavior such as increased drinking to fever, vomiting, and collapse. The treatment for both of these sequelae is surgical removal of the uterus and undescended testicles (orchidohysterectomy); however, genetic testing and prophylactic removal of the offending organs is probably the best way to treat this condition.
